PREFACE

The *Observatories' Year Book* was published for the years 1922 to 1937 in continuation of Part III Section II and Part IV of the *British Meteorological and Magnetic Year Book* for the period 1908 to 1921. Further publication was resumed eventually after a long interruption because of the 1939-45 war but in an abridged form as outlined in the next paragraph.

The General Introduction to the Meteorological Tables and the parts of the Sectional Introductions which dealt with site, instruments, procedure and tabulations included in the volume for 1938 served as the standards of reference up to 1956; only important departures from these standards were mentioned explicitly in subsequent Year Books. The space devoted to the discussion of observations was reduced and the monthly tables of individual hourly values of meteorological elements were discontinued, but summaries of the daily mean values (or totals), monthly means (or totals) of the hourly values and some maximum and minimum values were given. The diary of cloud, weather and visibility, and, after 1939, the aerological and seismological tables were also discontinued but no major changes were made in the tables of atmospheric electricity and geomagnetism.

Another major review of the contents of the *Observatories' Year Book* was then carried out and a number of important changes made, commencing with the volume for 1957. The meteorological data for Kew and Eskdalemuir were omitted; a punched card system of recording such data centrally, at the Meteorological Office, Bracknell has been adopted. It was also decided to omit all mention of the seismological work at Kew. Full details of the seismological measurements are given in the *Kew Seismological Bulletin*, distribution of which was resumed in 1947 after a break of seven years, and are also communicated to the *International Seismological Summary*. There were also some changes in the geomagnetism and atmospheric electricity tables; full details of the new tables are given in the Introduction to this volume.

It may be of assistance to those who make use of the data in this volume to know the full range of the other work now carried out at the three observatories and this is detailed below. Requests for information about this other work should be addressed to the Director-General, Meteorological Office, London Road, Bracknell, Berkshire.

Lerwick Observatory

Full hourly synoptic observations of the weather. Continuous recording and hourly tabulations of pressure, wind, rainfall, sunshine, temperature, humidity, total and diffuse solar radiation on a horizontal surface, daylight illumination on a horizontal surface. Daily measurements of evaporation and atmospheric pollution.

Routine radio sonde and radar wind upper air measurements (twice and four times daily respectively). Regular measurements normally several times a day, of the total amount of ozone. Chemical sampling of the air and rain water. Sampling for radioactivity of particulate matter in the air near the surface (from 17 September 1962) and sampling for radioactivity of rain water (from 1 October 1962).

Eskdalemuir Observatory

Full hourly synoptic observations 06·21 G.M.T. Continuous recording and hourly tabulations of pressure, wind, rainfall, sunshine, temperature, humidity, total and diffuse solar radiation on a horizontal surface, daylight illumination on a horizontal surface. Daily measurements of evaporation, atmospheric pollution and soil temperatures (at depths of 30 and 122 cm). Regular measurements, several times a day, of the total amount of ozone and occasional *umkehr* measurements of the vertical distribution. Chemical sampling of the air and

PREFACE (contd.)

rain water. Sampling for radioactivity of particulate matter in the air near the surface, sampling for radioactivity of rain water (from 23 August 1962).

Kew Observatory

Three-hourly synoptic observations 06-21 G.M.T. Continuous recording and hourly tabulations of pressure, wind, rainfall, sunshine, temperature, humidity, total and diffuse radiation on a horizontal surface, solar radiation at normal incidence, daylight illumination on a horizontal surface, net flux of radiation. Daily measurements of evaporation, and soil temperatures (at depths of 10, 20, 30 and 122 cm). Daily and hourly tabulations of atmospheric smoke pollution. Records from a set of Galitzin seismographs (3 components) and a short period vertical seismograph.

LERWICK OBSERVATORY

Geomagnetism

TABLES

1 Hourly values of horizontal component; hourly, daily and monthly sums and means 18
2 Hourly values of declination; hourly, daily and monthly sums and means 18
3 Hourly values of vertical component; hourly, daily and monthly sums and means 19
4 Daily extremes of magnetic elements, magnetic character figures (K and C) and temperature in magnetograph house 19
5 Mean monthly and annual values of magnetic elements 42
6 Monthly, seasonal and annual means of daily range 42
7 Frequency distribution of daily range 42
8 Diurnal inequalities of the magnetic elements, all days; monthly, seasonal and annual means 43
9 Diurnal inequalities of the magnetic elements, international quiet days; monthly, seasonal and annual means 44
10 Diurnal inequalities of the magnetic elements, international disturbed days; monthly, seasonal and annual means 45
11 Range of mean diurnal inequalities for the months, seasons and year 46
12 Average departure of diurnal inequalities from daily mean 46
13 Monthly, seasonal and annual values of non-cyclic changes of horizontal component, declination and vertical component 46
14 Average range of diurnal inequality 1932-53 with 1962 as a percentage of this 46
15 Ratio of range of inequality at Lerwick to that at Eskdalemuir 46
16 Noteworthy magnetic disturbances recorded at Lerwick 47

Aurora

17 Auroral log 48
18 General auroral table - British Isles 50

Atmospheric electricity

19 Hourly values of potential gradient, close to the ground over an open level surface; hourly, daily, monthly and annual means 52
20 Electrical character of each day and approximate duration of negative potential gradient 58

ESKDALEMUIR OBSERVATORY

Geomagnetism

21 Hourly values of horizontal component; hourly, daily and monthly sums and means 60
22 Hourly values of declination; hourly, daily and monthly sums and means 60

ESKDALEMUIR OBSERVATORY - *continued*

TABLES		PAGE
23	Hourly values of vertical component; hourly, daily and monthly sums and means	61
24	Daily extremes of magnetic elements, magnetic character figures (K and C) and temperature in magnetograph chamber	61
25	Mean monthly and annual values of magnetic elements	84
26	Monthly, seasonal and annual means of daily range	84
27	Frequency distribution of daily range	84

42	Electrical character of each day and approximate duration of negative potential gradient	110
43	Values of potential gradient, air-earth current and conductivity measured by the Wilson apparatus together with monthly and annual means	111

Atmospheric pollution

44	Monthly, seasonal and annual means for each hour	112

ERRATA IN PREVIOUS VOLUMES AND IN PRESENT VOLUME

Observatories' Year Books 1923 to 1961 inclusive

There are slight errors in the already published corrections to the declination for Lerwick for these years as mentioned for 1923-37 and listed for 1938 in the 1938 *Observatories' Year Book*, (see pages 20-21 for explanation) and as listed in subsequent *Year Books* up to 1946. Details are given in the present volume for 1962, page 8.

Observatories' Year Books 1934 to 1962 inclusive

For the reason given on page 2 of the present *Year Book* the true scale values which should have been taken for the *D* variometer in use at Lerwick for the periods here stated (the values hitherto adopted for *Observatories' Year Books* tabulations are given in brackets) are as follows:-

20 April 1934 to 30 September 1934, 0·97′/mm (0·99);
1 October 1934 to 29 March 1937, 0·97′/mm (0·95);
30 March 1937 to 31 December 1939, 1·04′/mm (1·00);
1 January 1940 to 25 September 1940, 1·04′/mm (1·03);
26 September 1940 to 23 July 1946, 0·97′/mm (0·99);
24 July 1946 to 3 November 1953, 0·97′/mm (0·95);
4 November 1953 to 31 December 1961, 0·97′/mm (0·96).

From 1 January 1962 the true value of 0·97′/mm has been used. At Eskdalemuir the periods and true values (values hitherto adopted being given in brackets) are:-

1 January 1936 to July 1939, 0·97′/mm (0·94);
After July 1939 to 31 December 1962, 0·93′/mm (0·90).

From 1 January 1963 the true value of 0·93′/mm has been used. The monthly and yearly mean values of *D* are unaffected, but the other values of *D* published in the *Observatories' Year Books* for Lerwick from April 1934 to December 1961 and for Eskdalemuir from January 1936 to December 1962, i.e. including the present volume, are in error by the proportion of their deviation from the mean monthly or yearly values; the correction is positive if the westerly declination is greater than the mean value and negative if it is less than the mean value. Tables containing quantities which involve the value of *D* are correspondingly affected.

Observatories' Year Book 1957

Page 12. In the third column of the first table the value for 1957 should be "-20" and not "-23" and for 1959 "-8" not "+14".

Observatories' Year Book 1958

Page 11. In the third column of the first table the value for 1957 should be "-20" and not "-23" and for 1959 "-8" not "+14".

Observatories' Year Book 1959

Page 12. Second line for "1959" read "1959 and 1960".

ERRATA IN PREVIOUS VOLUMES AND IN PRESENT VOLUME - (contd.)

Observatories' Year Book 1960

Page 9. Last paragraph, second line for "1959" read "1959 and 1960".

Page 10. Sixth line from the bottom, for the first "1948" read "1947" and for the second "1948" read "1946".

Fourth line from the bottom for "Since 1948" read "From 1947 onwards".

Page 21. Table 4, 10 January, for "1,1,1,3,4,8,5,5" read "1,1,3,3,4,8,5,5".

Page 29. Table 4, 1 May, for "6,6,3,4,4,3,2,4" read "6,6,4,3,4,3,2,4".

Page 29. Table 4, 28 May, for "2,2,2,1,2,2,2,4" read "2,2,2,1,2,2,4,4".

Page 43. Table 4, 22 December, under sum of *K* indices for "26" read "23".

Observatories' Year Book 1961

Page 5. UNDER NOTES ON THE RESULTS, first paragraph for "3·5′" read "4·3′", for "29" read "30" and for "10" read "13"

Page 10. Second paragraph, second line, for "(1959)" read "(1959 and 1960)".

Page 37. Table 4, 2 September, under Magnetic character of day, *C* for "1" read "0".

INTRODUCTION

DESCRIPTION OF OBSERVATORIES

Lerwick Observatory, Shetland (60°08′N, 1°11′W)

The Observatory is set on a ridge of high ground about 85 m above M.S.L. and about 2½ km to the south-west of the port of Lerwick (population about 6000). The surrounding country is desolate moorland.

General views of the Observatory, a site plan and a contour map of the surrounding country were published in the *Observatories' Year Book* for 1961. An account of the history of the Observatory is given by W.G. Harper (*Met. Mag., London* 79, 1950, p.309).

Eskdalemuir Observatory, Dumfriesshire (55°19′N, 3°12′W)

The Observatory is situated on a rising shoulder of open moorland about 245 m above M.S.L. in the upper part of the valley of the River White Esk in the Southern Uplands of Scotland. It is surrounded by open moorland with hills rising within 8 km to the north-west to nearly 700 m above M.S.L.

General views of the Observatory, a site plan and a contour map of the surrounding country were published in the *Observatories' Year Book* for 1961. The history of the Observatory is described by M.J. Blackwell in a paper marking the fiftieth anniversary of the commencement of observations (*Met. Mag., London* 87, 1958, p.129), and by J. Crichton (*Met. Mag., London* 79, 1950, p.337).

Kew Observatory, Richmond, Surrey (51°28′N, 0°19′W)

Kew Observatory lies in the centre of an area of parkland about 16 km west of the centre of London. The ground level is about 5 m above M.S.L. Outside the parkland within 1 km, the area is extremely built-up, with a number of small factories within a few kilometres to the north and east.

General views of the Observatory, a site plan and a contour map of the surrounding country were published in the *Observatories' Year Book* for 1961.

For the early history of the Observatory reference may be made to papers by G. Rigaud[1], R.H. Scott[2], C. Chree[3], O.J.R. Howarth[4], R.S. Whipple[5], F.J.W. Whipple[6] and A.J. Drummond[7].

GEOMAGNETISM

Regular recording of the earth's magnetic field commenced at Kew in 1857. By the beginning of the twentieth century however, the extension of London's electric railway and tramway system had caused so much magnetic disturbance that it was decided to establish another magnetic observatory in an area considered unlikely to be similarly affected. This led to the building of Eskdalemuir Observatory which was opened in 1908, but magnetic observations were also continued at Kew up to 1924.

Comparisons of the magnetic results obtained at Kew and Eskdalemuir showed, however, that it would be very desirable to obtain magnetic records as far north as possible in the British Isles, and this resulted in the establishment of Lerwick Observatory in 1921. Recording of the magnetic field has been continuous at Lerwick since January 1923.

The principal magnetographs at Lerwick and Eskdalemuir are standard and quick-run La Cour instruments, each set consisting of *H*, *D* and *Z* variometers. Time marks are made at five minute intervals except at the hour, and two minute breaks are made three times daily at Lerwick and twice daily at Eskdalemuir. Scale values of the *H* and *Z* variometers are measured about once a week at Lerwick and once a month at Eskdalemuir, during magnetically quiet periods, by passing a current through Helmholtz-Gaugain coils placed over the variometers, the resulting deflection being recorded on the photographic paper. The current is measured by a milliameter which is periodically calibrated or by a potentiometer using a standard resistance, and a standard cell. It is thought that the scale values adopted, about 4γ/mm for *H* and 6γ/mm for *Z* (at both observatories) are accurate to about ½ and 1 per cent respectively. The scale value for *D* is normally determined from the optics and geometry of the system, with small corrections for torsion and paper shrinkage, but is occasionally checked by a similar electrical method to that used with the *H* and *Z* variometers; the difference between the electrical and optical methods is small and the adopted scale values are accurate to about 1 per cent. Following a complete review, made in 1963-1964, of the scale values, used at both observatories since the installation of the La Cour variometers, in comparison with the optical calculations, electrical determinations and analyses of absolute values, it was decided that the values hitherto adopted were in error by amounts varying up to 4 per cent, mainly because geometrical calculations had been used alone, without account being taken of the curvature of the prism face. Details of the correct scale values to be adopted, over various periods, are given in the "*Errata in Previous Volumes and in the Present Volume*" section on page vii of the present *Year Book*. The monthly and yearly mean values of *D* are unaffected, but the other values of *D* published in the *Observatories' Year Books* for Lerwick from April 1934 to December 1961, and for Eskdalemuir from January 1936 to December 1962, i.e. including the present volume, are in error by the proportion of their deviation from the mean monthly or yearly values; the correction is positive if the westerly declination is greater than the mean value and negative if it is less than the mean value. Tables containing quantities which involve the value of *D* are correspondingly affected.

Complete sets (*H*, *D* and *Z*) of supplementary magnetographs with lower sensitivity are also operated to provide information during any breaks in the standard magnetograph records and also to provide information when rapid magnetic disturbance renders the traces of the standard magnetograph undecipherable. Details of these instruments can be found in the 1938 volume of the *Observatories' Year Book*.

The magnetograph house (*K**) at Lerwick, which contains the La Cour magnetographs, is above ground and is made of non-magnetic concrete: its internal dimensions are 4·9 m by 3 m with the semi-circular shaped roof about 3 m in the middle and 2 m at the sides, above the floor; the walls and roof are 76 cm thick. An electric heater, controlled by a thermostat, enables the temperature to be kept reasonably constant for periods of up to a few months at a time but power is insufficient to maintain the same temperature throughout the year. The thermostat is re-set by several degrees at a time, so as to reduce the number of changes to a minimum. The time for a cycle of temperature changes (that is, the time between successive operations of the thermostat contacts) is of the order of one hour and a small oscillation of the temperature of the magnetograph is evident from the records, but the amplitude is only about 1 degree Celsius. The supplementary magnetographs are housed in an unheated wooden hut (L).

*The descriptive letters or numbers are those given in the Figures published in the 1961 *Observatories' Year Book*.

At Eskdalemuir the magnetographs are placed in an underground chamber (3) constructed throughout of non-magnetic material. Within the outer shell of stone and concrete and separated therefrom, and from each other, by corridors and vaultings are two similar rooms of approximate internal dimensions - length 7·6 m, width 6·1 m, height 3·0 m. The ceilings of the room are slightly below the undisturbed level of the surrounding ground. The roof portion of the outer containing shell is covered with a thick layer of earth which forms a mound. Electrical heating, thermostatically controlled, was introduced in 1936 but, although the diurnal range in temperature is normally negligible, there is an annual range of temperature of about 4°C.

The temperature recorded by a thermometer inserted in the quick-run *Z* variometer, taken to be representative of the magnetograph house, is read daily at 09 G.M.T. and the readings are given in Table 4 (for Lerwick) and Table 24 (for Eskdalemuir).

Baseline values of the magnetograms are computed from the absolute measurements, made twice weekly, and measured scale values using the ordinate of the variometer curve at the times of the absolute observations. The adopted values of the baselines are obtained by a graphical smoothing process. Normally one value is adopted for one day except when instrumental discontinuities have occurred, but for Lerwick the temperature compensation of the *Z* variometer is not perfect and a baseline change of up to 5γ may occur when the thermostat is altered. The adopted baseline on these occasions is changed in 1γ steps so that the total change is spread over the period of temperature changes. (Towards the end of 1962, the temperature in the magnetograph house at Lerwick was deliberately changed through a range of about 9°C so as to enable the temperature coefficient of the *Z* variometer to be determined and then reduced.)

TABULATIONS

Tables 1 and 21 give, for Lerwick and Eskdalemuir respectively, mean values of the horizontal component *(H)* of magnetic force for periods of 60 minutes ending at the exact hour G.M.T. together with hourly, daily and monthly sums and means. Tables 2 and 22 give similar information for declination *(D)* and Tables 3 and 23 for the vertical component *(Z)*. Tables 4 and 24 contain the values of the daily extremes of each component, the range during the day and the magnetic character figures *K* and *C*, together with the 09h. temperature in the magnetograph house.

Tables 1-4 are subdivided into monthly sections and the same monthly parts of each table are grouped together on facing pages. Tables 21-24 are treated similarly. The days selected by the International Association of Geomagnetism and Aeronomy (I.A.G.A.) as being typical "quiet" and "disturbed" days are marked by the letters "*q*" and "*d*" respectively.

In general the declination *(D)* is measured to the west, and is considered to increase with increasing westerly declination, in accordance with the convention adopted in previous volumes. There is, however, an important exception in Tables 16 and 38 entitled "Noteworthy Magnetic Disturbances" (see below). In these two tables a movement of *D* to the east (that is, decreasing westerly declination) is regarded as positive, in order that the data in the tables may agree in every respect with data already supplied to I.A.G.A.

The magnetic character figures *C* are determined merely by inspection of the magnetograms. The standard is related to the general level of activity during the year, and the following recommendations, made in 1910 by Chree, Van Everdingen and Schmidt are adopted as guiding principles "that no one of the characters, 0, 1 and 2 should be attributed to more than two thirds of the days of the year, and that in each quarter the number of days of character 2 should be on the average at least 6".

The magnetic character figures *K* have been derived generally in the conventional way (see for example, I.G.Y. Instruction Manual Part IV Geomagnetism - Part I section 1.7) except

that, from 1957, a slightly different method of drawing the non-*K*-variation curves was adopted. At Lerwick this non-*K*-variation curve was drawn from a template, the slope of which could be adjusted to allow for post-perturbation effects; three seasonal templates (for winter, equinox and summer) were used; they were based on the mean quiet day diurnal variations over the 11-year period 1935-45. At Eskdalemuir the similar procedure was more detailed in that six two-monthly (December and January, November and February, October and March, September and April, August and May and June and July) curves of quiet day inequalities, for 1945-55, were prepared in several amplitudes, the curve giving the best fit being chosen, and allowance made by tilting the scales for non-cyclic changes and post-perturbation effects. The lower limit for $K=9$ is 1000γ for Lerwick and 750γ for Eskdalemuir.

From 1 January 1963 the non-*K*-variation curves have been drawn exactly in the manner recommended by the I.G.Y. Manual.

Tables 5 (for Lerwick) and 25 (for Eskdalemuir) give the mean monthly and annual values of the magnetic elements *H*, *D* and *Z* together with the values of the North Component (*X*), West Component (−*Y*), Inclination (*I*) and Total Force (*F*). The values for *H*, *D* and *Z* are also given for the international quiet and disturbed days.

Tables 6 and 7 (for Lerwick) and 26 and 27 (for Eskdalemuir) give monthly, seasonal and annual means and frequency distributions of the daily range for each component (*H*, *D* and *Z*). For this purpose "Winter" is defined as the four months November to February; "Equinox" as March, April, September and October, "Summer" as May to August.

The next set of tables (8-15 for Lerwick and 28-36 for Eskdalemuir) gives data on the diurnal inequalities of each magnetic element. As recommended by a resolution of the Commission for Terrestrial Magnetism and Atmospheric Electricity and approved by the Conference of Directors at Warsaw in 1935, the diurnal inequalities are all uncorrected for non-cyclic change, but the values of the non-cyclic change are also given separately in Tables 13 and 35. It was decided to rearrange the order of the magnetic elements in Lerwick Tables 14 and 15 and in Eskdalemuir Table 36, commencing with the 1960 *Observatories' Year Book*, to conform with the other magnetic tables, that is, in the standard order of *H*, *D* and *Z*.

Some information is given for Eskdalemuir but not for Lerwick. This includes the diurnal inequalities of the North (*X*) and West (−*Y*) components and the Inclination (*I*), and values of the first four harmonic components of the diurnal inequalities of the north, west and vertical components.

The inequalities of *X*, −*Y* and *I* have been computed from those of *H*, *D* and *Z* by means of the formulae:

$$\delta X = \cos D.\delta H - \frac{\pi}{180 \times 60} H \sin D.\delta D$$

$$-\delta Y = \sin D.\delta H + \frac{\pi}{180 \times 60} H \cos D.\delta D$$

$$\delta I = \frac{180 \times 60}{\pi} \cos I \left[\frac{\delta Z \cos I - \delta H \sin I}{H}\right]$$

in which δD and δI are expressed in minutes of arc, and *H*, *D* and *I* for any given month are the respective mean values for that month as published in Table 25.

The results of harmonic analysis of the mean diurnal inequalities of X, $-Y$ and Z for the months, seasons and year are to be found in Table 37, in which are given the values of a_n, b_n, c_n and α_n in the two equivalent series $\Sigma\,(a_n\cos 15nt^\circ + b_n\sin 15nt^\circ)$ and $\Sigma\, c_n\sin(15nt^\circ + \alpha_n)$. In the former series t is reckoned in hours from midnight G.M.T., whilst the published values of α_n refer to local mean time. The harmonic coefficients have been computed from the inequalities as given in Tables 28-33 but for this purpose the non-cyclic change has been eliminated. A correction has been applied where necessary, because the hourly values are not instantaneous but are mean values; the factors by which the coefficients have to be multiplied (see *Report of the British Association*, 1883, p.98) are 1·00286 for a_1, b_1, and c_1; 1·01152 for a_2, b_2 and c_2; 1·02617 for a_3, b_3 and c_3; and 1·04720 for a_4, b_4 and c_4. The values were obtained to two decimal places and finally were rounded off to 0·1γ.

Tables 16 and 38 are entitled "Noteworthy Magnetic Disturbances". These were revised in content in 1947 and now include all the disturbances which would have been included in the previous type of tables, with however, additional disturbances with sudden commencement (ssc) and those which can be recognised as being solar flare effects (sfe). The tables are divided into three parts:

(a) Disturbances noteworthy for some reason (usually, but not always, range) and without a sudden commencement.

(b) Well marked sudden commencements whether followed by a large disturbance or not.

(c) Disturbances accompanying a solar flare or other known solar flare effect.

The time given of commencement and ending of disturbances in (a) must depend on an arbitrary judgement. The list of sudden commencements under (b) will usually be a little shorter than that given in the I.A.G.A. bulletins because a somewhat stricter meaning has been been given to the words "well marked". (An attempt, made in 1961, to time the events in the (b) table to 0·1 minute was not considered to be satisfactory, and the timing has now reverted to the nearest minute). The (c) table has been made as complete as possible by a careful scrutiny of the magnetograms at the time of any known solar flare or solar flare effect, but a small "crochet" can easily be masked by other disturbances. Doubtful cases are not included. The signs given to the movements of H, D and Z are positive for increasing H, Z and an increase of force towards the east (that is, a decreasing westerly declination). Particulars of the same disturbances are given in both the Lerwick and Eskdalemuir tables, even if the disturbance at one of the stations is relatively small.

NOTES ON THE RESULTS

Comparing mean values on all days of 1962 with those of 1961, at Lerwick H increased by 26γ, D (west) decreased by 6·4′ and Z increased by 11γ. The changes deduced in X, Y, I and F are +29γ −19γ, −1·5′ and +19γ respectively. The ranges between the extreme values recorded during 1962 were H 1067γ, D 2°8·7′ and Z 699γ. The range of 2°8·7′ in declination corresponded to a range of 546γ in the component of force perpendicular to the magnetic meridian.

Similarly at Eskdalemuir H increased by 33γ, D (west) decreased by 5·2′ and Z increased by 11γ. The changes deduced in X, Y, I and F are +38γ, −19γ, −2·0′ and +22γ respectively. The ranges between the extreme values recorded during 1962 were H 317γ, D 1°18·3′ and Z 317γ. The range of 1°18·3′ in declination corresponded to a range of 383γ in the component of force perpendicular to the magnetic meridian.

ABSOLUTE STANDARDS OF MAGNETIC FORCE AT LERWICK AND ESKDALEMUIR

Vertical Component

The older instruments in use before the introduction of proton precession magnetometers in 1960, and the results obtained by inter-observatory comparisons using BMZ's are described

in the 1957, 1958 and 1959 *Observatories' Year Books*. (In 1963 errors were found on checking the 1957 and 1959 inter-observatory comparisons; the true values for 1957 and 1959 for entry in the third column of the first table on page 12 of the 1957 *Observatories' Year Book* and in the third column of the first table on page 11 of the 1958 *Observatories' Year Book* are -20 and -8 respectively).

During 1960 proton precession magnetometers were installed at Lerwick and at Eskdalemuir. The principle of these instruments has been described by Packard and Varian[1] and Waters and Francis[2].

They enable the free precession frequency (f) of the proton to be measured; this is related to the total magnetic field F at the proton sample by the relation

$$f = \frac{\gamma_p F}{2\pi}$$

where f is in cycles per seconds and γ_p is the gyromagnetic ratio of the proton. The value adopted for γ_p is $2{\cdot}67513 \times 10^4$ radians gauss^{-1} sec^{-1}[5]; this is the value as measured by Driscoll and Bender[3,4] and recommended provisionally at the meeting of the International Association of Geomagnetism and Aeronomy in Helsinki in 1960[5].

The proton sample used at Lerwick and Eskdalemuir is distilled water contained in a polythene bottle, 11·5 cm long and 6 cm diameter placed on the axis of a solenoid. (At Lerwick the centre of the bottle is 42½ cm above the top of the west pier in the old Absolute hut (H); at Eskdalemuir it is 74 cm above a pier in the East hut (2)). This solenoid serves firstly to provide a strong polarising field and then as a pick-up coil to detect the small precession signal. After amplification the signal is passed to a counter unit to enable its periodicity to be determined. This is done by measuring the time, in units of 10 microseconds, for a given number of cycles of precession. Usually 2048 cycles are counted; this gives an accuracy of 1 part in 10^5 (or 0·5γ) when measuring the total field or the vertical component in the British Isles, because the value of f for these fields is close to 2000 cycles per second and the counting time is therefore about 1 second. The timing of the cycles is by means of a 100 kc/s oscillator, the accuracy of which is checked by beating its first harmonic against the B.B.C. Light Programme carrier wave, the frequency of which is 200 kc/s. It has been proved by experiment that the magnetic fields of the amplifier and counter units at the pick-up coil are less than 0·1γ.

At Lerwick routine absolute measurements of the total field are made twice daily and in each week two or three of those made during quiet periods are selected for calculations of the vertical component assuming the Observatory H record is correct. At Eskdalemuir total field measurements are made twice weekly coinciding with the absolute observations for H and D during quiet periods. The equation used is

$$Z = \sqrt{F^2 - H^2}$$

and it is easily shown that the error ΔZ in Z caused by an error ΔH in the H measurements is given by

$$\Delta Z = -\left(\frac{H}{Z}\right)\Delta H.$$

The ratio (H/Z) at Eskdalemuir and Lerwick is about ⅓. Since it is believed that the systematic errors in H do not exceed 6γ (and may well be much less) the corresponding error in Z is small (2γ or less). The 1960 comparison over a period of two months (May-June, Eskdalemuir; June-July, Lerwick) of the proton magnetometer Z values (denoted here by Z_{pm}) with the Z values obtained by using the Schulze dip inductor (Eskdalemuir, denoted here Z_{DIP}) and B.M.Z.83 (Lerwick) yield the following mean results.

$$\text{Eskdalemuir} \qquad Z_{pm} - Z_{DIP} = 0\gamma,$$

$$\text{Lerwick} \qquad Z_{pm} - Z_{BMZ83} = -8{\cdot}5\gamma.$$

At Lerwick the proton magnetometer, using the Schuster-Smith value of H, has been accepted as the standard instrument for measuring Z since 1 August 1961. However, as there is still some uncertainty due to the uncertainty in H baseline values, which will be removed when the proton vector magnetometer is brought into use, it was considered preferable to make no discontinuity in the Z baseline until absolute determinations are made; accordingly the accepted Z baseline was derived from the relation

$$Z = Z_{pm} + 9\gamma.$$

This, in effect, continued the B.M.Z.83 baseline. After the proton magnetometer had been use during the remainder of 1961 it was decided that it would be more accurate to use Z values derived directly from it. This, together with a movement of the proton bottle in the old Absolute hut (H), from a shelf to the west pier, caused a discontinuity, from 1 January 1962, of -7γ with the previous Z baseline.

An upper limit to the magnitude of the random errors of the proton magnetometer can be estimated from the constancy of the Z baseline measurements. Over a period of 2 months in 1960 at Lerwick comprising observations on 33 days the standard deviation of a single observed Z baseline about a mean value was $1{\cdot}7\gamma$. This of course included the variability of both the Z and H baselines of the variometers and the errors in reading two sets of ordinates from the charts; the effect of these cannot be estimated accurately but must certainly account for the greater part of the observed variability of the baseline measurements. It is probable that the random error of the proton magnetometer is due solely to the short term random error of the frequency measuring apparatus (1 part in 10^5, as mentioned earlier). The limits of error were similar in 1962.

Experimental proton vector magnetometers have been in use at both observatories during the year; the water bottle is at the centre of a rotatable Helmholtz-Gaugain coil system. Preliminary results suggest no significant change is required in the existing Z baselines.

The finally constructed proton vector magnetometers, which will be described in a later volume of the *Observatories' Year Book* will be designated as the standard absolute instruments. A complete account will then be given of the finally adopted Z baselines and of their relation to previous values.

Horizontal Component

The history of the determinations of the absolute values of the horizontal component, *H*, at Eskdalemuir and Lerwick is given on pages 8 to 10 of the 1961 *Observatories' Year Book*. No change was made in the existing methods of determination in 1962, but preliminary results with the experimental proton vector magnetometers in 1962 indicate that the existing *H* baseline is about 3γ too high at both observatories. A complete account of the history and present value of the *H* baselines will be given when the final proton vector magnetometers are in use.

Declination

It was decided in 1963 to re-examine all the available manuscript data on the determination of the azimuth of the fixed mark at Lerwick, from the first measurement in 1922 to the most recent value in 1961. (Measurements were made in 1922, 1923, 1930, 1932, 1937, 1938, 1939, 1940, 1944, 1948 and 1961, the last two being by the Ordnance Survey.) The clear conclusion was reached that the apparent drift of the mark between 1923 and 1948 mentioned in the 1938 and subsequent *Observatories' Year Books* was not real and was due to errors of observation with the instruments available at Lerwick. The most accurate observation ($08^{\circ}38{\cdot}8' \pm 4''$ east of south) is that made by the Ordnance Survey in 1961, and it is considered that this has always been the true value since declination observations began in 1922. This conclusion is consistent with the geology of the region, since both concrete pillars - that on which the declinometer stands, and that, 117 m away on which the azimuth mark is placed are firmly cemented into solid bedrock. The change from the already published corrections for the years 1923 to 1946 are that (i) the original 1923 determination was in error by $4{\cdot}2'$ and not $3{\cdot}5'$, and (ii) that this figure of $4{\cdot}2'$ is the amount by which westerly declination is too large between 1923 and 1946, and not the range from $3{\cdot}5'$ in 1923 to $4{\cdot}4'$ in 1946, hitherto mentioned. In addition the published values of westerly declination from 1947 to 7 November 1961 are too small by $0{\cdot}2'$.

The observations of the azimuth of the fixed mark at Eskdalemuir in 1948 gave results negligibly different from previous observations and no changes were required in the tabulations. Further observations of the fixed mark at Eskdalemuir were made in July 1961, by the Observatory staff, using a Tavistock theodolite, with Polaris as a reference star. The value determined was only 7" (and the standard deviation of the observations was 6") from the value adopted after the Ordnance Survey determination in 1948. The 1961 value was brought into use on 1 September 1961, and, with the scatter in baseline values, the effect of the change on declination measurements was negligibly small.

MAGNETIC SURVEY AT LERWICK OBSERVATORY

In July 1962 a survey of the total field *F* over an area of 120 x 90 metres containing the Lerwick Observatory huts, was made using two proton magnetometers. This followed a similar survey, with one proton magnetometer, made in the previous year. These surveys indicate that there is no marked anomaly in *F* over this area, except very near to the cloud searchlight (17) caused probably by the searchlight transformer and equipment in Hut M. Over the rest of the area the field may be taken as fairly uniform, within the limits of experimental error. The gradient was 10γ per 100 metres in a direction 142°, i.e. the northward gradient of *F* is $-0{\cdot}08\gamma$/metre and eastward gradient $0{\cdot}06\gamma$/metre.

In 1937 a survey of the vertical force *Z* was made with a B.M. magnetometer covering an area within 1 to 2 km of the Observatory. This showed that the gradient of *Z* was $0{\cdot}08\gamma$/metre towards SE approximately. Admiralty charts mark a magnetic anomaly 20 km SSE of the Observatory.

AURORA

A special watch for Aurora is kept at Lerwick Observatory. Up to 2200h each evening observations of the northern horizon and general meteorological conditions are made at intervals of 15 to 20 minutes; if any aurorae are seen continuous observations are made and details of the phenomena observed are noted. If necessary a second observer is called. Elevations of significant points are measured with a simple alidade.

Any aurorae which commence after 2200h are also noted by the staff making regular synoptic observations and upper air soundings, but these staff may not be able to devote long periods solely to recording the detailed auroral changes.

A brief account of the results obtained is given in Table 17. All dates, on which the sky remained completely overcast throughout the night and on which, therefore, no opportunity arose of determining whether or not aurora occurred, have been omitted. Those nights on which aurora was actually observed are indicated by the symbol ⏀; other nights on which no aurora was observed, despite at least an occasional interval of more or less clear sky, are indicated by the symbol ••. In the latter case also, remarks on the weather are added to assist the reader in judging how far the fact of no observation of aurora may be taken as showing that, in fact, there was no aurora. Each night is described by a letter code which has the following significance:-

a = Conditions favourable for seeing aurora
b = Unfavourable for faint aurora (because of moonlight, mist, thin cloud etc.), but not such as to mask bright aurora
c = Cloudy, but aurora not seen in clear intervals
ca, cb = Cloudy, but with conditions a or b respectively, in the intervals. Changing conditions are indicated by a hyphen; for example, a-c.

The detailed observations are available in manuscript and have also been sent to Mr. J. Paton of the Balfour Stewart Auroral Laboratory, University of Edinburgh.

Table 18 is a general auroral table giving a summary of the observations of aurorae in the British Isles. It is compiled from the detailed observations received at the Balfour Stewart Auroral Laboratory. A detailed examination of the tables for 1957 and 1958 has been made by B. McInnes and K. A. Robertson in a paper published in the *Journal of Atmospheric and Terrestrial Physics*, 19, 1960, p.115.

ATMOSPHERIC ELECTRICITY

The programme at Lerwick and Eskdalemuir is to maintain a continuous record of atmospheric electric potential gradient as it exists just above a natural open level surface. This is also done at Kew Observatory but there, in addition, regular measurements are made on fine afternoons of the air-earth current. These latter are expressed as mean values covering the period of observation which is normally about 20 minutes centred on about 1430 G.M.T.

Continuous Potential Gradient measurements

The instruments used for the recording of the potential gradient are similar in principle at all three observatories. An insulated boom projects through the wall of the building and takes up the potential of the air because of the ionisation caused by a small

radio-active collector fitted to its tip. The potential of the boom is recorded by an electrostatic voltmeter. The use of valve voltmeters for these measurements is discussed below.

The collectors are of polonium deposited on a copper rod about 4 cm long by 0·5 cm diameter; these are recoated periodically by arrangement with the Government Chemist and a fresh collector is brought into use each quarter. Tests at Kew Observatory in 1959 showed that the strength of a new collector is usually between 80 and 200 micro-curies. A note about the supply of the collectors and of the techniques used in plating them is given in *Nature* 1955, 175, p.965.

The potential of the boom is of course affected by the presence of buildings, although it is assumed that this potential is always proportional to the potential gradient in the open. Standardising measurements have therefore to be made of the true potential gradient at a suitable open site. The ratio of the potential gradient in the open to the potential of the boom is called the exposure factor and is expressed in the units (metre^{-1}).

The methods of making the standardisation measurements of potential gradient are different at each observatory.

At Lerwick an insulated wire with a polonium collector fixed to its centre is stretched horizontally between two stout wooden posts 9 m apart. The centre of the wire is exactly 1 m above a levelled piece of ground. The potential of this wire is observed at 1 minute intervals for a period of 10-20 minutes using a Wulf electrometer. From the mean value of the observed potential and the mean reading of the electrograph an exposure factor is calculated. Observations are made in fine weather and as many as possible are made. Smoothed monthly means of the factors so obtained are used in the reduction of the records.

At Eskdalemuir absolute observations of potential gradient are made with a Wulf electrometer using a small pit about 50 yards from the main building. The electrometer is placed inside the pit and from the electrometer a thin metal rod (0·4 cm in diameter) projects vertically upwards through a hole in the metal lid covering the pit. A polonium collector is fixed to the rod at exactly one metre above the ground level. It has been shown experimentally that the potential of the rod is the same (within experimental error) as that of a stretched wire at one metre exposed to the same potential gradient.

The observer shuts himself in the pit and takes readings of the electrometer every half minute until 15-30 readings have been obtained. As at Lerwick observations are made in fine weather and at least six per month are aimed at. From the mean potential of the Wulf electrometer over the period and the corresponding mean value of the record, the exposure factor of the electrograph is obtained.

For any given month a mean exposure factor is used and this is a smoothed running mean using observations made during the preceding and following months.

The absolute measurements at Kew are made with the Wilson apparatus in the underground laboratory; these are described below.

At Lerwick the Benndorf electrograph, which had been the standard recording instrument since 1926, was replaced on 1 January 1961 by the valve voltmeter electrograph. This electrograph had been recording in a position similar to that of the Benndorf electrograph since 1959; the boom projected about 80 cm through a window, and about 420 cm above the ground. On 13 July 1961 this electrograph was moved into the newly constructed observatory buildings. In its new position the boom projects 58 cm from the north-east wall of the electrograph room at a height of 206 cm above the ground. The instrument is 160 m from the site of the absolute potential gradient measurements. A site plan, Fig.3, in the *1961 Observatories' Year Book* shows the old and new positions of the electrograph and the site of the absolute potential gradient measurements.

The valve voltmeter electrograph is constructed on the pattern described by A. W. Brewer (*Journal of Scientific Instruments*, 30, 1953, p.91). A pen record is obtained on a chart, 7·5 cm wide, which normally moves at a speed of 1·2 cm per hour, but the speed can be increased if required.

The scale value of the electrograph is 3 volts per mm on its sensitive scale, and about 15 volts per mm on its insensitive scale. The boom is automatically earthed at each hour, and then operates on the sensitive scale. When the voltage exceeds 90 volts, the electrograph automatically changes to its insensitive scale. Full scale deflection on the insensitive scale is obtained with about 540 volts, so with an exposure factor of around 2·5 the electrograph can record a range of +1350 to −1350 volts per metre in the open. Scale value measurements are made once weekly, using dry batteries and a calibrated voltmeter. The insulation is tested daily and, even in wet weather, is good. In fine weather the rate of leak is so small, that the time taken for the instrument to lose half its potential has never been measured; only after 15 minutes has a movement of the pen been detectable.

Tests of the rate of rise of potential of the electrograph and boom with the polonium collector fitted are made at intervals. The time taken for the potential to rise to half its final value is 2-3 seconds. The rate of leak is thus so very much less than the rate of charging that the difference between the potential of the boom and that of the air surrounding it is negligible.

The electrograph at Eskdalemuir consists essentially of a quadrant electrometer with a small mirror on the vane which reflects a light spot on to a sheet of bromide paper wrapped around a drum rotated by clockwork. From 1936 until 1954 the electrograph boom projected through a pipe in the north wall a few feet to the west of its present position; it now projects through a wooden door.

The boom is supported on insulators, formerly of sulphur but, since October 1957, of polythene. Tests of the insulation of the boom and electrograph are made frequently (about 3 times per week). The insulation was in general very satisfactory throughout the year.

The scale value of the record was approximately 1·8 volts per millimetre during 1962 and this, combined with an exposure factor of about 8, means that one millimetre on the record corresponded approximately to 14 volts per metre in the potential gradient over an open level surface.

The Kew electrograph, which is also a quadrant electrometer recording photographically, was moved in April 1940 from a low building known as the Clinical House to a room in the main Observatory Building; the new position is 18 m to the east of the former position. In March 1941 a metal fire escape was erected on this wall above the boom and this reduced the recorded potential by nearly 50%. This was compensated by increasing the sensitivity of the recorder by an approximately similar amount. The radioactive collector is now 90 cm from the window of the building through which the boom projects and 360 cm above ground level.

The scale value of the electrograph has been fixed at about 17 volts per metre per millimetre.

The electrograph became unreliable in May 1953 and from then until the end of 1955 the continuous records of potential gradient have not been published. Reliable recording started again on 1 January 1956.

Valve voltmeters, as now in use at Lerwick, have also been recording continuously at Kew since May 1958, and at Eskdalemuir since April 1959, in addition to the electrograph voltmeters.

Air-earth current and conductivity measurements at Kew

Measurements of the air-earth current and potential gradient are made in an underground laboratory using a modified Wilson apparatus. From these observations the conductivity can be calculated. The apparatus was devised by C. T. R. Wilson* and is described in detail by F. J. Scrase†. Briefly, it consists of an insulated brass plate, mounted with its top surface flush with the ground level, and connected to a sensitive electrometer. The test plate can be covered when necessary with an earthed cylindrical cover, and can be maintained at any desired potential (usually zero) by a small charged variable capacitor (called the compensator). The method of using the instrument at Kew differs slightly from that adopted by Wilson, who used the readings of the position of the compensator to obtain the charge on the test plate. At Kew the compensator is used merely to keep the plate at zero potential, and the charge is measured by reading the deflection of the electrometer. The potential gradient is measured by the charge induced on the plate when it is exposed to the earth's field, and the air-earth current is measured by finding the charge collected by the plate during a known period (usually five minutes).

The potential gradient F is given in volts per centimetre by the formula

$$F = 4\pi\ (9 \times 10^{11})\ Cv/A$$

where C is the capacity, in farads, of the system (when shielded), v is the potential acquired by the test plate after being exposed to the field, earthed and then shielded, and A is the area of the test plate‡. The potential gradient found in this way is, to a close approximation, equal to that found by measuring the potential at a height of 1 m in the open part of the grounds with a stretched wire apparatus.

The air-earth current is given in amperes per square centimetre by the formula

$$i = C\delta v/At$$

where δv is the potential acquired by the plate in t seconds. The value of δv used is the mean result from four observations, each lasting five minutes. The observations of the current are sandwiched between measurements of the field strength, and from the mean values of i and F the conductivity λ is deduced. This conductivity is that due to positive ions only since measurements are made only with positive fields. No observations are made in precipitation and fog.

From 1 July 1949 to the end of 1955 trouble was experienced with the Wilson test plate apparatus and the observations of air-earth current and conductivity during the period have subsequently been found to be unreliable. These observations have not therefore been published.

---

*WILSON, C.T.R.; *Proc. Camb. phil. Soc., London*, 13, 1906, pp.184 and 363.

†SCRASE, F.J.; *Geophys. Mem., London*, 7, No.60, 1934.

‡In practice, at present, half the potential gradient observations are made by a slightly different procedure, less desirable in principle, but giving negligibly different results; the plate is shielded, earthed and then exposed to the field and its potential measured.

The observations of the potential gradient with this apparatus during this time were checked, however, on a number of occasions by simultaneous observations of the potential of a stretched wire at one metre above the ground level; the differences between the two methods of observations occasionally reached 15 per cent but the mean difference was only 4 per cent, the Wilson measurements being the greater. In view of the trouble with the apparatus it was decided that from July 1949 onwards until the end of 1955 the stretched wire observations should be the standard and that, before being used for electrograph standardisations, the Wilson observations should be corrected to allow for the differences between the two. Throughout this doubtful period the observations of potential gradient with the Wilson apparatus have been considered of sufficient value to publish, but the differences found between these observations and those made with the stretched wire apparatus must be borne in mind.

The instrument was overhauled late in 1955 and from 1 January 1956 the records and tabulations are considered reliable.

TABULATIONS

Tables 19 (for Lerwick), 39 (for Eskdalemuir) and 41 (for Kew) contain the mean values of the potential gradient for periods of 60 minutes ending at exact hours G.M.T. The entry for these hours, however, for which the mean is indeterminate because of large fluctuations, is made according to the following code:- Z+ means an indeterminate but positive value, Z- an indeterminate but negative value and Z± an hour when the gradient was indeterminate in both magnitude and sign. In addition the entry for hours when precipitation is observed or recorded is marked with an asterisk.

Mean values and sums are given for each hour and for the months and year, using only hours without precipitation and for which the entry is not Z. The number of hours used for each mean is given. Estimated values are entered in brackets and are included in the sums and means. Besides this the monthly and annual mean potential gradients are given, using only the entries for 0a days (or for "selected quiet days" at Kew Observatory). The definition of 0a days is given in the next paragraph; the definition of "selected quiet days" at Kew is as follows:- normally 10 quiet days are selected in each month, these being calendar days characterised by no negative potential gradient, no large irregular movements, no indication of inferior insulation and no large non-cyclic change. When there are not 10 calendar days in a month the number can sometimes be made up by using other spells of 24 hours. The purpose of these entries is to enable comparison to be made with previous years for which corresponding information has been published.

In Tables 20, 40 and 42 (for Lerwick, Eskdalemuir and Kew respectively) the duration of negative potential is tabulated and an electrical character figure is assigned to each day.

At Kew the following scheme is used for the latter entries:-

0 denotes a day during which, midnight to midnight, no negative potentisl was recorded.

1 denotes the existence of nagative potential at one or more times during the same period but with a total duration of less than three hours.

2 denotes negative potential extending in the aggregate to three hours or more during the same period.

Besides allocating each day a number as done at Kew, Lerwick and Eskdalemuir observatories also allocate to each day a symbol, either "a", "b" or "c". The definition of these is as

follows:-

a denotes that within the 24 periods of 60 minutes, for which an estimate of the mean potential gradient has to be made, there was in no case a range of potential gradient in the open exceeding 1000 volts per metre.

b denotes that a range of 1000 volts per metre or more was reached in one hour at least, but in fewer than six individual hours.

c denotes that a range of 1000 volts per metre or more was reached in at least six individual hours.

During periods of defective record the sign of the gradient is assumed positive when no precipitation was recorded. If precipitation was recorded for less than one hour during such defective periods, an approximate value for the duration of negative potential for that hour has been assigned and the total for the day is given in brackets. If this cannot be done the entry for any day with a defective record is "-". When, because of oscillating gradients, there is uncertainty as to the times of change of sign, half the total duration of doubtful sign is accounted negative. When by reason of defective record there is some doubt as to the correctness of either the character number or letter or both, round brackets are put around the doubtful entry.

Table 43 contains the results of the measurements of the potential gradient, air-earth current and conductivity due to positive ions made with the Wilson apparatus at Kew. Each entry is the mean value for a period of twenty minutes centred about 1430 G.M.T. on the date in question. Monthly and annual means are also given.

It should be pointed out that the unit of potential gradient is volts per centimetre (not volts per metre as in the other tables); the unit of air-earth current is 10^{-18} ampere per square centimetre and the unit of conductivity is 10^{18} per ohm per centimetre.

NOTES ON THE RESULTS

While no detailed discussion of the results is attempted here it is perhaps of interest to point out that marked changes have occurred since around 1951; those occurring in the period 1951-1959 were discussed by K. H. Stewart in the *Quarterly Journal of the Royal Meteorological Society*, 86, 1960, p.399 and attributed to the deposition on the ground of radioactive debris from nuclear explosions for test purposes. The results obtained since 1959 appear to confirm this hypothesis; the changes continue to be linked with the frequency of tests.

ATMOSPHERIC POLLUTION

On 1 January 1962 the use of the Owens atmospheric pollution recorder at Kew Observatory was discontinued and the new Department of Scientific and Industrial Research (D.S.I.R.) recorder became the standard instrument for measuring the diurnal variation of atmospheric pollution. This was foreshadowed when the new recorder was described in the Introduction to the 1961 *Observatories' Year Book*. This description is repeated below for convenience; for a description of the Owens instrument reference should be made to the Report on observations in the year 1917-18, *London Meteorological Office, Advisory Committee on Atmospheric Pollution*. The new recorder was installed during February 1961 in the building known as the Clinical House, with the level of the intake about two metres above that of the adjacent ground.

The new recorder was designed at the Warren Spring Laboratory of the D.S.I.R. and operates on a similar principle to their standard daily filters. Air is drawn by a small pump through a filter and thence through an air meter. The filter material is, however, a continuous roll of glass fibre "paper", and the clamp, which defines the area of the paper through which the air is drawn, can be released automatically by a time switch. When this happens the filter paper is also wound on a suitable distance, so that when the clamp is allowed to reposition itself the air is drawn through a fresh area of the paper and a new stain is produced.

The instrument is operated from an hourly time switch so that 24 stains are produced every day. The air meter is only read once a day but it has been found that by using a constant voltage transformer to supply the power for the electric pump the rate of air flow is extremely constant. During periods of light pollution a pump sucking 5·5 cu ft an hour is used but during times of heavy pollution a different pump sucking only 2·8 cu ft an hour is used.

The stains are much larger in diameter than those produced by the Owens recorder and the optical density is measured with a photoelectric reflectometer. This result is a much more accurate and sensitive reading. It is estimated that the minimum concentration of smoke that can be reliably detected by this apparatus is about 0·005 milligrams per cubic metre whereas with the Owens instrument the limit is at least twenty times this value.

The relation between the reflectance of the glass fibre stain, the volume of air passed and the smoke concentration was not known at the beginning of this work. A reliable calibration has however been determined at Kew by comparing the results from daily and hourly measurements on the same day. Full details of this calibration are given in a paper by R. H. Collingbourne and H. E. Painter[1].

The new instrument was run side by side with the Owens recorder for 10 months in 1961 and considerable systematic differences were found between the results of the two instruments. These were only in part due to the greater sensitivity of the new instrument. In the table below is given the mean relation between the monthly mean hourly values of smoke concentration as found from the two instruments.

Relation between Monthly mean hourly values of smoke concentration as found by the two recording instruments in 1961
unit: milligrams per cubic metre

Owens	D.S.I.R.	Owens	D.S.I.R.
·075	·027	·16	·23
·10	·045	·20	·31
·12	·085	·30	·46
·14	·175		

It is seen that the Owens instrument reads too high at low concentrations and too low at high concentrations. It undoubtedly well underestimates the peak concentrations. A fuller discussion of the comparison between the Owens instrument and the new recorder is in preparation; meanwhile the discontinuity in the records should be noted. The average diurnal

[1] COLLINGBOURNE, R.H. and PAINTER, H.E.; A smoke filter curve for glass fibre filter paper type AGF/A. *Air Wat. Poll., London*, 8, 1964, p.159.

change in atmospheric pollution will also be much more accurately measured with the new instrument.

A summary of the results obtained at Kew is given in Table 44. In this table are hourly means of the concentration of suspended matter, in milligrams per cubic metre, for each month, the seasons and the year. Winter is taken as the months January, February, November and December, Spring as March and April, Summer as May to August and Autumn as September and October.

The data from this instrument are also published in a different form in the various Reports of the Atmospheric Pollution Research Committee, (D.S.I.R., "*The Investigation of Atmospheric Pollution*", H.M.S.O. published yearly). The results of the observations made with the daily smoke filters for Kew, Eskdalemuir and Lerwick are also published in these volumes.

During 1962 the highest estimate of pollution at Kew was 3·5 mg/m^3, this value occurring from 16-17 hours on 5th December.

There were three days on which the mean hourly concentration of pollution reached 1·0 mg/m^3.

The number of hours credited with 1·0 mg/m^3 or more was forty-five, all of which occurred in December; thirty-six from 3rd-7th December, two on 19th December and seven on the 22nd December. However, due to freezing fog causing a blockage in the inlet pipe to the instrument, no hourly measurements were possible from 20 hours on 3rd December to 14 hours on 4th December and from 20 hours on 4th December to 09 hours on 5th December and it is probable that the concentration during most of these thirty-one hours exceeded 1·0 mg/m^3.

Late in 1960 there was also installed at Kew Observatory, on behalf of D.S.I.R., apparatus for the measurement of the concentration of sulphur dioxide in the atmosphere. Air which has already been passed through the daily smoke filter is bubbled through a weak solution of hydrogen peroxide causing the sulphur dioxide to be converted to sulphuric acid and to remain in solution. The acidity of the hydrogen peroxide solution is then found by titration against a 1/250 normal solution of sodium borate, using B.D.H.4·5 (a narrow range indicator); from this result, knowing the volume of air, the average sulphur dioxide concentration can be calculated. Measurements are made once daily and, since January 1961, the results have been passed at monthly intervals to D.S.I.R. and published by them alongside the smoke pollution data (see above).

A full description of this method of measuring the sulphur dioxide concentration (together with other methods of measuring atmospheric pollution) is given in the D.S.I.R. publication "*Measurement of Air Pollution*", (London, H.M.S.O. 1957).

NOTE ON THE TABLES: Where figures are in italics they are maximum and/or minimum values. All times are in G.M.T.

q denotes an international quiet day and *d* an international disturbed day.

MEAN MONTHLY AND ANNUAL VALUES OF GEOMAGNETIC ELEMENTS

For all, *a*, quiet, *q*, and disturbed, *d*, days for *H*, *D* and *Z* and for all days for *X*, *-Y*, *I* and *F*

17 LERWICK

Night commencing			Night commencing			Night commencing		
JANUARY			**MARCH (contd.)**			**AUGUST (contd.)**		
1	ca-c ..	Partly cloudy soon becoming cloudy	7	c-a ..	Cloudy becoming fair later	14	ca ..	Partly cloudy
2	ca-a-ca ..	Variable then fine then variable	10	a ⌀	Fine. A moderately bright arc at 22h.50m. became active with rays at 23h. and persisted until 23h.38m. when it gradually died to a glow at 23h.50m., and remained so until a brighter arc developed at 02h.15m. with rays becoming more active at 02h.30m., gradually fading to a faint glow at 02h.45m.	15	ca-a-ca ⌀	Partly cloudy then fine, then partly cloudy. Homogeneous arc at 00h.20m., with rays between 01h.02-05m., was obliterated by dawn at 01h.50m.
3	ca-a-ca ..	Variable then fine then variable						
5	a ..	Mainly fair						
6	ca-c ..	Partly cloudy then cloudy						
7	ca-a-ca ..	Variable then fine then variable						
8	c-ca ..	Mainly cloudy				16	c ..	Mainly cloudy
9	ca-a ..	Variable				17	c ..	Mainly cloudy
10	ca-a-ca ⌀	Variable then cloudy. A bright glow to N. at 22h.50m., with rays observed at 23h.10m., persisted until 23h.50m., when it was obscured by cloud				18	a-c ..	Fair becoming mainly cloudy
						21	c ..	Mainly cloudy
						22	cb ⌀	Partly cloudy or cloudy. Rays were seen at 22h.30m. and a glow at 22h.40m.
			11	cb-b ..	Mainly fair. Moonlight			
			12	cb ..	Variable. Moonlight			
11	c-ca-a ..	Cloudy then variable	13	cb ..	Partly cloudy. Moonlight	23	c ..	Cloudy becoming mainly cloudy
13	cb-a ..	Variable. Moonlight early part of night	14	ca-b ..	Fair to fine with moonlight	25	ca ..	Very variable cloud
			15	c ..	Mainly cloudy	27	a-c ..	Partly cloudy becoming mainly cloudy
14	c ..	Mainly cloudy	16	c ..	Mainly cloudy			
16	ca ..	Partly cloudy	17	c ..	Mainly cloudy	28	c ..	Partly cloudy or cloudy
17	b-ca ..	Variable. Moonlight early night	18	c-cb ..	Variable to cloudy. Moonlight	29	c-a ..	Cloudy becoming partly cloudy
18	ca-cb ..	Variable. Moonlight	19	c-cb ..	Cloudy or partly cloudy	30	a-ca ..	Fair or fine becoming mainly cloudy
19	c-b-ca ..	Cloudy then fine, then partly cloudy. Moonlight	21	c ..	Mainly cloudy to cloudy			
			22	cb-c ..	Partly cloudy to cloudy. Moonlight			
20	cb-c-ca ..	Partly cloudy, then cloudy, then partly cloudy. Moonlight	23	ca ..	Mainly cloudy to partly cloudy			
			26	c-ca-a ..	Cloudy to fair then fine			
21	cb ..	Variable. Moonlight	27	ca-a ..	Fair			
22	cb ..	Variable. Moonlight	28	a ⌀	Fine. A faint glow persisted from 23h.30m. to dawn			**SEPTEMBER**
23	a-ca ..	Fine to variable. Cloudy later on				2	ca-a-c ..	Mainly cloudy to fair then cloudy
24	ca-a-b ..	Variable then fine. Moonlight	30	c ..	Mainly cloudy			
25	c-cb ..	Cloudy then partly cloudy. Moonlight	31	a-c ..	Mainly fine becoming cloudy	3	c ..	Mainly cloudy then cloudy
						5	a-c ..	Mainly fine
26	ca-a ⌀	Variable or fine. Faint glow to N. at 20h.				6	c ..	Cloudy becoming partly cloudy
						7	c ..	Partly cloudy, then cloudy, then partly cloudy
27	a-ca ..	Mainly fine then partly cloudy			**APRIL**			
28	a-c ..	Variable then cloudy				8	c ..	Partly cloudy then cloudy
29	c ..	Mainly cloudy	1	a-ca ⌀	Variable. Faint glow seen at 20h.45m. behind cloud	9	cb-c ⌀	Partly cloudy and moonlight then cloudy. A glow persisted between 21h.30m. and 00h.55m.
31	ca ..	Variable						
			3	ca ..	Variable			
			4	ca-a ..	Variable then fine	10	cb ..	Partly cloudy and moonlight
			5	c-ca ..	Cloudy then variable	11	cb-b ..	Partly cloudy becoming fine with moonlight
		FEBRUARY	6	a ⌀	Fine. From 20h.44m. to 21h.13m. a rayed arc was observed with rays to zenith at 20h.45m. and 21h.13m. Between 21h.15m. and 23h.30m. a faint homogeneous arc or diffuse surface was present, fading to a glow at 23h.30m. At 00h.05m. the display was renewed with a bright curtain of rays. Between 00h.15m. and 01h.15m. a homogeneous band on diffuse surface gradually faded away	12	cb ..	Very variable cloud and moonlight
1	a-ca ..	Variable				13	cb ..	Partly cloudy and moonlight
2	c-a-ca ..	Cloudy then variable				15	a-c ..	Very variable but mainly fair
3	ca ..	Variable				16	c ..	Mainly cloudy
4	ca-a ⌀	Variable. A glow at 20h.40m. was obscured by cloud at 20h.54m. At 21h.55m. a diffuse surface was seen through cloud gaps				17	c ..	Variable cloud
						18	c ..	Mainly cloudy
						21	c ..	Mainly cloudy
						22	a-c ..	Mainly fine becoming cloudy
5	ca-c ..	Variable then cloudy				23	c-cb ..	Cloudy becoming partly cloudy and moonlight
7	ca-c ..	Variable then cloudy						
9	c-ca ..	Cloudy then partly cloudy				24	a ⌀	Fine. An arc with occasional rays was seen at 20h.50m. and a glow at 21h.30m. and 21h.50m.
10	ca ..	Mainly cloudy						
11	c-ca ⌀	Cloudy then variable. At 02h.50m. a glow was seen to N.	7	a ⌀	Fine. A quiet homogeneous arc persisted between 21h.30m. and 23h.30m.	25	c-a-c ..	Mainly cloudy with brief fine interval about 23h.
12	ca-cb ..	Mainly cloudy then variable. Moonlight	8	a-ca ..	Variable	27	c-a ..	Cloudy becoming fine
			9	c-ca ..	Mainly cloudy becoming fair	29	a-c ⌀	Fine to partly cloudy to cloudy. A glow to north was seen between 19h.42m. and 00h.15m.
13	cb-ca ..	Variable or cloudy. Moonlight	10	a-c ⌀	Fair becoming cloudy. A diffuse glow was seen behind cloud at 21h.15m.			
14	c ..	Mainly cloudy						
15	c-ca ..	Cloudy then partly cloudy						
16	cb ..	Cloudy or partly cloudy. Moonlight				30	a-ca ..	Mainly fair or fine becoming partly cloudy
18	c-cb ..	Mainly cloudy then partly cloudy. Moonlight	11	c-cb ..	Cloudy to partly cloudy. Moonlight			
			12	b ..	Fair. Moonlight			
19	c-b-cb ..	Cloudy to fine then partly cloudy. Moonlight	13	b ..	Fair becoming fine. Moonlight			
			14	b-ca ..	Fine becoming partly cloudy. Moonlight			
20	ca-cb-ca ..	Partly cloudy to variable then partly cloudy. Moonlight	15	a-ca-b ..	Fine to cloudy to fair. Moonlight			**OCTOBER**
21	ca-c ..	Variable then cloudy	16	b ..	Fine. Moonlight	1	a ⌀	Fine. A quiet homogeneous arc persisted between 19h.40m. and 21h.50m. A glow at 22h.50m. became a pulsating surface with rays at 22h.55m. A glow was again seen between 23h.10m. and 23h.20m. with a pulsating surface at 23h.14m.
22	a-ca ..	Mainly fine	17	cb-b-c ..	Fair becoming cloudy. Moonlight			
23	ca-c ..	Mainly cloudy	18	b-ca ..	Fair then variable. Moonlight			
24	c-ca ..	Mainly cloudy	21	ca ..	Partly cloudy			
25	ca-c ..	Cloudy or variable	25	c-ca ..	Cloudy then partly cloudy			
26	ca-c ..	Partly cloudy soon overcast	26	ca-c-ca ..	Mainly cloudy then partly cloudy			
27	ca ..	Mainly cloudy	27	a ..	Fine			
28	ca ..	Variable	28	a ..	Fine			
			29	ca ..	Partly cloudy	2	c ..	Partly cloudy with brief fine interval at midnight
						3	c ..	Variable cloud
		MARCH				5	a-ca ..	Fair to fine to fair
					AUGUST	6	c-a-ca ..	Cloudy becoming variable
1	c-ca ..	Cloudy then variable				7	a-c ⌀	Fine becoming cloudy. A faint glow was seen at 21h.53m.
2	c-ca ..	Variable	1	c-a ..	Mainly cloudy becoming fine			
3	ca-c ..	Variable then cloudy	2	c ..	Mainly cloudy	8	c-a-c ..	Cloudy with brief fine interval at 01h.
4	a ⌀	Mainly fine. A diffuse surface was seen at 00h.30m. and 04h.50m.	4	c ..	Mainly cloudy			
			5	ac ..	Partly cloudy	10	ca ..	Partly cloudy
			6	a-c ..	Fine becoming cloudy	11	c ..	Mainly cloudy
5	a ⌀	Mainly fine. A faint glow at 21h.30m. with a ray for a few seconds at 21h.31m. persisted until 01h. From 03h. until dawn faint rays above a diffuse surface were seen at various times	7	a-ca ..	Fine becoming partly cloudy	12	c ..	Mainly cloudy
			8	a-ca ..	Partly cloudy	13	cb ..	Variable cloud and moonlight
			9	c ..	Mainly cloudy	15	c ..	Partly cloudy becoming foggy
			10	a-ca ..	Fine becoming cloudy	18	cb ..	Very variable cloud
			11	ca-c ..	Partly cloudy	19	c ..	Partly cloudy becoming cloudy
			12	c-ca ..	Cloudy becoming partly cloudy			
			13	a ..	Variable cloud	20	c ..	Mainly cloudy

17 LERWICK (contd.) 1962

Night commencing			Night commencing			Night commencing		
	OCTOBER			NOVEMBER (contd.)			DECEMBER (contd.)	
21	c-b-c ..	Cloudy becoming fair and moonlight then cloudy	16	b	⏀	Variable cloud and moonlight. At 19h.45m. a rayed band appeared suddenly but had disappeared by 20h.05m.	11 c-cb ..	Cloudy becoming variable and moonlight
23	c ..	Very variable cloud					12 cb ..	Variable cloud and moonlight
25	c-ca ⏀	Partly cloudy. A faint glow was seen between 22h.40m. and 23h.30m.	17	a-b ..		Fair	13 c ..	Mainly cloudy
			18	ca-b ..		Very variable cloud	14 cb ..	Variable cloud and moonlight
26	ca-c ⏀	Partly cloudy becoming cloudy. A faint glow was observed intermittently between 18h.48m. and 20h.45m.	19	ca-c ..		Partly cloudy becoming cloudy	15 c-cb ..	Cloudy becoming variable and moonlight
			20	ca-b ..		Very variable cloud - moonlight later	16 c-b ..	Variable becoming fine and moonlight
			21	a-b	⏀	Mainly fine. A faint glow between 17h.30m. and 01h.45m. brightened to a double homogeneous arc until 01h.50m. Between 02h.15m. and 03h.05m. a homogeneous arc persisted, with occasional bundles of bright rays. A quiet glow or arc was seen between 03h.15m. and 04h.45m.	17 c	⏀	Variable cloud. A faint glow was observed between 17h.30m. and 18h.34m.
27	c ..	Variable cloud								
28	ca ..	Very variable cloud								
29	c-ca ..	Cloudy becoming fair or fine					18 ca-cb	⏀	Variable cloud with fine spells. A faint glow at 18h.55m. developed into a homogeneous arc at 19h.08m. reverting to a glow by 19h.15m. At 19h.30m. and 20h.04m. rays of varying intensity were seen. The glow persisted until 00h.15m.
30	ca ..	Very variable cloud								
31	ca ⏀	Very variable cloud. A faint glow was seen intermittently between 22h.35m. and 01h.20m.								
			22	ca-c ..		Partly cloudy becoming cloudy				
	NOVEMBER		23	c ..		Cloudy with brief clear interval at 05h.	19 a-c	⏀	Fine becoming cloudy. A glow at 19h.10m. became an arc of varying intensity at 20h.25m. until suddenly fading at 21h.15m. to appear again, as suddenly, at 21h.17m. with faint ray, fading to a glow by 21h.27m. until 00h.30m.
3	ca ⏀	Variable cloud. A faint glow at 21h.50m.	24	a-c ..		Mainly fine becoming cloudy				
4	ca ..	Partly cloudy	25	c-ca ..		Cloudy becoming variable				
6	c-ca ..	Cloudy then variable	26	ca ..		Very variable				
7	c-ca ..	Cloudy until 05h. then partly cloudy	27	c-ca ..		Cloudy becoming variable				
			29	a	⏀	Mainly fine. A faint glow or arc with occasional rays persisted between 18h.54m. and 19h.55m. An arc was again seen at 01h.52m. and 02h.				
9	c-cb ..	Mainly cloudy with occasional fair intervals					20 c ..		Cloudy becoming variable	
10	c ..	Mainly cloudy					21 a-c	⏀	Fine becoming variable. A rayed arc at 18h.50m. became a very faint glow by 18h.58m. brightening to a homogeneous band at 20h.10m. Flaming rays were seen at 20h.28m. The glow, with a bright ray at 20h.39m., persisted until 21h.25m.
11	b-cb ..	Mainly fine becoming partly cloudy	30	ca ..		Very variable				
12	c-b ⏀	Variable cloud. Very faint glow was seen at 00h.								
13	c-a ..	Mainly cloudy becoming partly cloudy								
14	cb ..	Very variable cloud and moonlight		DECEMBER						
15	b ⏀	Variable cloud and moonlight					22 a ..		Fair or fine	
		A faint glow at 19h.30m. became a bright flaming rayed band at 20h.45-47m. A glow, with rays at 21h.07 and 08m., was seen between 21h.05m. and 21h.12m. An active rayed arc of varying brightness was present between 23h.35m. and 00h.05m.	1	c ..		Cloudy or variable	25 c-a ..		Cloudy becoming fine	
			2	c ..		Variable cloud	26 c ..		Very variable cloud	
			3	c ..		Partly cloudy becoming cloudy	27 ca ..		Very variable cloud	
			5	cb-ca ..		Fine to fair becoming cloudy	28 ca	⏀	Very variable cloud. A faint glow was seen at 21h.40m.	
			6	c ..		Mainly cloudy becoming variable				
			8	c ..		Partly cloudy	29 a-ca ..		Fine becoming variable	
			9	cb-c ..		Variable cloud and moonlight	30 ca ..		Very variable	
			10	c ..		Cloudy	31 a ..		Fair becoming fine	

In the interests of brevity there have been omitted from Table 17 all dates on which the sky throughout the night remained completely overcast and on which therefore, no opportunity arose of determining whether or not aurora occurred. The nights on which aurora was actually seen are indicated by the symbol ⏀. The nights on which aurora was not seen despite at least an occasional interval of more or less clear sky, are indicated by the symbol ..; in the latter case also, remarks on the weather are added to assist the reader in judging how far the fact of no observation of aurora may be taken as indicating that there was not actual aurora.

The letters a, b, c, have the following significance:-

a = Conditions favourable for seeing aurora
b = Unfavourable for faint aurora (because of moonlight, mist, thin cloud etc.), but not such as to mask bright aurora
c = Cloudy, but aurora not seen in clear intervals
ca,cb = Cloudy, but with conditions a or b respectively, in the intervals
Changing conditions are indicated by a hypen; for example, a-c.

The above table was compiled in the Balfour Stewart Auroral Laboratory of the University of Edinburgh from all data available for the longitude of the British Isles, using mainly observations made at British Meteorological Office stations and by British voluntary observers, but including also some of the data from the Faroes, from Ireland and from France. Acknowledgements are made to the Directors of the Meteorological Services of Denmark (for the Faroes data). Ireland and France.

In the table, Φ_1 is the lowest geomagnetic latitude from which aurora was seen in the longitudes considered. On any night, if more than a horizon glow was seen from the British Isles, the other forms reported are listed and the period of time (G.M.T.) during which the display was observed from the British Isles is stated. The standard abbreviations are used for the forms and types of activity: G = horizon glow; HA = homogeneous arc; RA = rayed arc; HB = homogeneous band; RB = rayed band; R = rays; S = surface; P = pulsating; F = flaming. If the forms could not be determined because of cloud or twilight, but auroral light was positively identified, the abbreviation L is used. Under Φ_2 is given the lowest geomagnetic latitude of overhead occurrence in the longitudes considered. In the absence of direct visual observations, Φ_2 is deduced from elevation measurements made in other latitudes, assuming a height of 100 Km. for the lower edges of arcs and bands.

Because of varying observing conditions, these data are in some cases incomplete; aurora may have been overhead in latitudes lower than those listed, and other forms may have occurred. Fuller details may be obtained from the Laboratory on request.

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean value for periods of sixty minutes between exact hours

																						Mean for 0a days			[72	(5)]

The potential gradient is reckoned as positive when the potential increases upwards. The symbol Z indicates either that the trace fluctuates rapidly so that estimation of a mean value is impracticable, or that the trace is limited by the range of the instrument (see Introduction); and the suffix +, - or ± indicates that the mean value is plainly positive, plainly negative, or indeterminate in sign. The occurrence of precipitation of any sort is indicated by an asterisk. Round brackets round any hourly mean indicates that the record during that hour is somehow imperfect.

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean value for periods of sixty minutes between exact hours

																						Mean for 0a days			[86	(10)]

Daily, monthly and annual means are computed excluding hours with precipitation and, of course, all indeterminate entries. The number of hours or days used in computing each mean is shown in round brackets. Entries in square brackets are means for 0a days (see Introduction) and the figure in round brackets is the number of days used in computing this mean.

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean value for periods of sixty minutes between exact hours

																								Mean of 0a days	[97	(5)]

The potential gradient is reckoned as positive when the potential increases upwards. The symbol Z indicates either that the trace fluctuates rapidly so that estimation of a mean value is impracticable, or that the trace is limited by the range of the instrument (see Introduction); and the suffix +, - or ± indicates that the mean value is plainly positive, plainly negative, or indeterminate in sign. The occurrence of precipitation of any sort is indicated by an asterisk. Round brackets round any hourly mean indicates that the record during that hour is somehow imperfect.

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean value for periods of sixty minutes between exact hours

																								Mean for 0a days	107	(8)

Daily, monthly and annual means are computed excluding hours with precipitation and, of course, all indeterminate entries. The number of hours or days used in computing each mean is shown in round brackets. Entries in square brackets are means for 0a days (see Introduction) and the figure in round brackets is the number of days used in computing this mean.

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean value for periods of sixty minutes between exact hours

																						Mean for 0a days			[146	(4)]

The potential gradient is reckoned as positive when the potential increases upwards. The symbol Z indicates either that the trace fluctuates rapidly so that estimation of a mean value is impracticable, or that the trace is limited by the range of the instrument (see Introduction); and the suffix +, - or ± indicates that the mean value is plainly positive, plainly negative, or indeterminate in sign. The occurrence of precipitation of any sort is indicated by an asterisk. Round brackets round any hourly mean indicates that the record during that hour is somehow imperfect.

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean value for periods of sixty minutes between exact hours

																						Mean for 0a days			[97	(7)]

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean value for periods of sixty minutes between exact hours

19 LERWICK — Factor 1·95 — DECEMBER 1962

																								Annual mean for 0a days		[91]

Daily, monthly and annual means are computed excluding hours with precipitation and, of course, all indeterminate entries. The number of hours or days used in computing each mean is shown in round brackets. Entries in square brackets are means for 0a days (see Introduction) and the figure in round brackets is the number of days used in computing this mean.

q denotes an international quiet day and *d* an international disturbed day.

GEOMAGNETIC FORCE: HORIZONTAL COMPONENT

Mean values for periods of sixty minutes ending at exact hours, G.M.T.

q denotes an international quiet day and *d* an international disturbed day.

GEOMAGNETIC FORCE: HORIZONTAL COMPONENT

Mean values for periods of sixty minutes ending at exact hours, G.M.T.

21 ESKDALEMUIR (H) — 16,000γ (0·16 C.G.S. unit) + — DECEMBER 1962

q denotes an international quiet day and *d* an international disturbed day.

MEAN MONTHLY AND ANNUAL VALUES OF GEOMAGNETIC ELEMENTS

For all, *a*, quiet, *q*, and disturbed, *d*, days for *H*, *D* and *Z* and for all days for *X*, *-Y*, *I* and *F*

25 ESKDALEMUIR 1962

"Winter" comprises for four months January, February, November, December; "Equinox" the months March, April, September, October: and "Summer" May to August.

DIURNAL INEQUALITIES OF THE MAGNETIC ELEMENTS, DECLINATION, INCLINATION, AND HORIZONTAL COMPONENT

ALL DAYS

Departures from the mean of the 24 hourly values (uncorrected for non-cyclic change)

29 ESKDALEMUIR 1962

DECLINATION (measured positive towards the west)

"Winter" comprises the four months January, February, November, December; "Equinox" the months March, April, September, October; and "Summer" May to August.

RANGE OF MEAN DIURNAL INEQUALITIES FOR THE MONTHS, YEAR AND SEASONS OF 1962

The ranges are derived from the diurnal inequalities printed in Tables 28 to 33

34 ESKDALEMUIR 1962

"Winter" comprises the four months January, February, November, December; "Equinox" the months March, April, September, October; and "Summer" May to August.

HARMONIC COMPONENTS OF THE DIURNAL INEQUALITY OF MAGNETIC FORCE

Values of a_n, b_n in the series $\Sigma(a_n \cos 15nt + b_n \sin 15nt)$, t being reckoned in hours from midnight G.M.T.

Longitude of Eskdalemuir Observatory, 3°12′W.

																									Mean for 0a days	[76 (1)]

The potential gradient is reckoned as positive when the potential increases upwards. The symbol Z indicates either that the trace fluctuates rapidly so that estimation of a mean value is impracticable, or that the trace is limited by the range of the instrument (see Introduction); and the suffix +, - or ± indicates that the mean value is plainly positive, plainly negative, or indeterminate in sign. The occurrence of precipitation of any sort is indicated by an asterisk. Round brackets round any hourly mean indicates that the record during that hour is somehow imperfect.

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean value for periods of sixty minutes between exact hours

																								Mean for 0a days	[47	(1)]

Daily, monthly and annual means are computed excluding hours with precipitation and, of course, all indeterminate entries. The number of hours or days used in computing each mean is shown in round brackets. Entries in square brackets are means for 0a days (see Introduction) and the figure in round brackets is the number of days used in computing this mean.

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean values for periods of sixty minutes between exact hours

																								Mean for 0a days	[43	(4)]

The potential gradient is reckoned as positive when the potential increases upwards. The symbol Z indicates either that the trace fluctuates rapidly so that estimation of a mean value is impracticable, or that the trace is limited by the range of the instrument (see Introduction); and the suffix +, − or ± indicates that the mean value is plainly positive, plainly negative, or indeterminate in sign. The occurrence of precipitation of any sort is indicated by an asterisk. Round brackets round any hourly mean indicates that the record during that hour is somehow imperfect.

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean value for periods of sixty minutes between exact hours

																								Mean for 0a days	[58	(4)]

Daily, monthly and annual means are computed excluding hours with precipitation and, of course, all indeterminate entries. The number of hours or days used in computing each mean is shown in round brackets. Entries in square brackets are means for 0a days (see Introduction) and the figure in round brackets is the number of days used in computing this mean.

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean value for periods of sixty minutes between exact hours

																								Mean for 0a days	[62	(2)]

The potential gradient is reckoned as positive when the potential increases upwards. The symbol Z indicates either that the trace fluctuates rapidly so that estimation of a mean value is impracticable, or that the trace is limited by the range of the instrument (see Introduction): and the suffix +, − or ± indicates that the mean value is plainly positive, plainly negative, or indeterminate in sign. The occurrence of precipitation of any sort is indicated by an asterisk. Round brackets round any hourly mean indicates that the record during that hour is somehow imperfect.

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean value for periods of sixty minutes between exact hours

																							Annual mean for 0a days		[77]

Daily, monthly and annual means are computed excluding hours with precipitation and, of course, all indeterminate entries. The number of hours or days used in computing each mean is shown in round brackets. Entries in square brackets are means for 0a days (see Introduction) and the figure in round brackets is the number of days used in computing this mean.

																									Mean for selected quiet days	[285 (10)]

The potential gradient is reckoned as positive when the potential increases upwards. The symbol Z indicates either that the trace fluctuates rapidly so that estimation of a mean value is impracticable, or that the trace is limited by the range of the instrument (see Introduction): and the suffix +, - or ± indicates that the mean value is plainly positive, plainly negative, or indeterminate in sign. The occurrence of precipitation of any sort is indicated by an asterisk. Round brackets round any hourly mean indicates that the record during that hour is somehow imperfect.

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean value for periods of sixty minutes between exact hours

																									Mean for selected quiet days	[268 (10)]

Daily, monthly and annual means are computed excluding hours with precipitation an, of course, all indeterminate netties. The number of hours or days used in computing each mean is shown in round brackets. Entries in square brackets are means for selected quiet days (see Introduction) and the figure in round brackets is the number of days used in computing this mean.

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean value for periods of sixty minutes between exact hours

																									Mean for selected quiet days	[179 (10)]

The potential gradient is reckoned as positive when the potential increases upwards. The symbol Z indicates either that the trace fluctuates rapidly so that estimation of a mean value is impracticable, or that the trace is limited by the range of the instrument (see Introduction): and the suffix +, - or ± indicates that the mean value is plainly positive, plainly negative, or indeterminate in sign. The occurrence of precipitation of any sort is indicated by an asterisk. Round brackets round any hourly mean indicates that the record during that hour is somehow imperfect.

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean value for periods of sixty minutes between exact hours

																									Mean for selected quiet days	[171 (10)]

Daily, monthly and annual means are computed excluding hours with precipitation and, of course, all indeterminate entries. The number of hours or days used in computing each mean is shown in round brackets. Entries in square brackets are means for selected quiet days (see Introduction) and the figure in round brackets is the number of days used in computing this mean.

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean value for periods of sixty minutes between exact hours

Factor 4·82

																									Mean for selected quiet days	[253 (10)]

The potential gradient is reckoned as positive when the potential increases upwards. The symbol Z indicates either that the trace fluctuates rapidly so that estimation of a mean value is impracticable, or that the trace is limited by the range of the instrument (see Introduction); and the suffix +, - or ± indicates that the mean value is plainly positive, plainly negative, or indeterminate in sign. The occurrence of precipitation of any sort is indicated by an asterisk. Round brackets round any hourly mean indicates that the record during that hour is somehow imperfect.

POTENTIAL GRADIENT (close to the ground, over an open level surface).
Mean value for periods of sixty minutes between exact hours

																					Annual mean for selected quiet days					[246]

Daily, monthly and annual means are computed excluding hours with precipitation and, of course, all indeterminate entries. The number of hours or days used in computing each mean is shown in round brackets. Entries in square brackets are means for selected quiet days (see Introduction) and the figure in round brackets is the number of days used in computing this mean.

ELECTRICAL OBSERVATIONS, UNDERGROUND LABORATORY, WILSON METHOD

Mean value for periods of twenty minutes about 14h. 30m. G.M.T.

F = Potential gradient, unit 1 v.cm.$^{-1}$. i = Air-earth current, unit 10^{-18} amp. cm.$^{-2}$

$\lambda+$ = Conductivity due to positive ions, unit 10^{-18} ohm.$^{-1}$ cm.$^{-1}$
